#### **Content overview**

The Knowledge and Development Centre (KDC) is a foundation which objective is to support the development of the Mainport Schiphol. Within KDC, the sector partners KLM, RSG and LVNL co-operate coordinate their development activities and cooperate with knowledge institutes such as the Dutch Aerospace Laboratory, the NLR.

The research and development activities in KDC are managed on the basis of a KDC research agenda. The research agenda contains a description of studies that are currently active as well as proposed research topics. Furthermore, this document is used to set priorities between projects whilst maintaining a clear overview of proposed research questions. Research projects become active when the KDC board has given a formal 'go ahead', based on a study plan (or proposal) and the financial proposal by the KDC management team.

### 1 Introduction

The Knowledge and Development Centre (KDC) is a foundation which objective is to support the development of Schiphol as a Mainport. Within KDC, the sector partners KLM, RSG and LVNL co-operate with knowledge institutes such as the Dutch aerospace laboratory NLR, Delft University of Technology, <u>Amsterdam University of Applied Sciences</u> and the Dutch meteorology institute KNMI. Industry partnerships are also incorporated within the KDC construction.

The KDC research agenda contains a work programme for the development of Mainport Schiphol, in particular the airside part of the Schiphol operation. Studies which require the involvement of multiple sector partners or knowledge institutes are candidate studies for the KDC Research agenda. KDC can initiate research projects if requested by e.g. the government (i.e. the Department of Infrastructure and Water Management) or by one of the sector partners. The objective of the research agenda is to provide guidance to the work program 2021 and beyond. The KDC research agenda is a multi-annual agenda with a time horizon of five years.

The research agenda 2021 – 2025 will be executed within the context of the post-corona period which will be characterized by a gradual recovery of global aviation. With the recovery, reduction of the environmental footprint of aviation will become increasingly important. Other contextual developments for the KDC research agenda are:

- The national airspace re-design programme has identified a large number of technological and logistical innovations which need to be developed in support of the future airspace concept. The required developments include new capacity management techniques, in support of stable and predictable traffic handling.
- With the implementation of iCAS as the next generation ATM system by LVNL, the transition to Trajectory Based Operations (TBO) will become an important theme. TBO is the enabler for the "next-level performance" of the ATM system, in the area of safety, flight efficiency and environmental sustainability.

Important policy links for the KDC research area are the national airspace redesign programme, and the programme to reduce noise annoyance (<u>minderhinderschiphol.nl</u>).

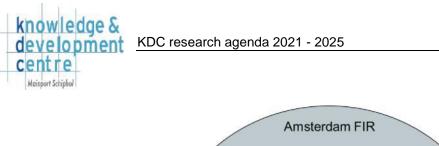

### 1.1 Structure of the Agenda

The agenda is structured as follows: chapter 2 presents the scope and strategic objectives of the programme for the duration of the programme. Chapter 3 presents the focus for the next year, as part of the multi-year programme. Chapter 4 presents the descriptions of the development subjects. The development subjects are clustered around the strategic objectives for the ATM system in terms of performance.

The five research agenda clusters are:

- 1. Safe Airspace and Airport Navigation
- 2. Environmental sustainability
- 3. Airline and Airport Operational Efficiency
- 4. Capacity Management
- 5. Airspace Redesign & Innovation

In figure 1 below, these clusters have been projected on a horizontal plane, indicating for which parts of the Airport/Airspace system the clusters are applicable.

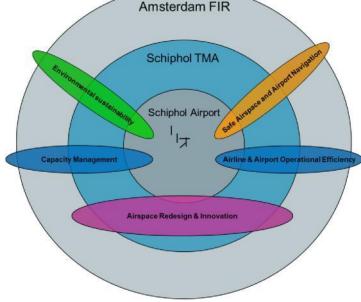

Figure 1: Research subjects projected on airport - airspace structure

### 2 KDC research agenda

The KDC sets itself the task of offering valuable and useful solutions for the sustainable development of the Mainport Schiphol. This task is executed by defining and realizing target orientated projects with close consultation of both the air transport sector and the government (Dept. of Infrastructure & Water Management).

### 2.1 Scope

The scope of KDC-projects varies from applied research to the development of executable system concept. Examples are: technology explorations, ATM-process analysis and simulations, concept development, feasibility studies, performance analysis (e.g. economical security aspects and/or environmental aspects).

Fundamental/basic research is considered outside the scope of the KDC. This is considered to be a task of the universities and knowledge institutes. Engineering and realisation (implementation) is a responsibility of the individual sector partner and are normally also considered outside the scope of the KDC.

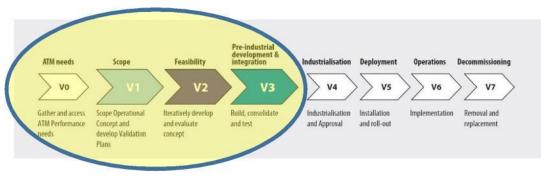

Figure 2: Scope of KDC-projects

For each KDC subject a Technology Readiness Level (TRL) and a E-OCVM CLM phase has been determined. The TRLs are a systematic metric/measurement system that supports assessments of the maturity of a particular technology and the consistent comparison of maturity between different types of technology. The TRL scale varies from TRL 1 to TRL 9. A more detailed description of the TRLs may be retrieved in Appendix A.

The E-OVM methodology is described by Eurocontrol as a framework to provide structure and transparency to the validation of operational ATM-concepts, from early phases of development towards implementation. The complete lifecycle is subdivided into eight 'V' phases. The principal relation between the TRLs and Concept Lifecycle Model (CLM) phases is shown in the figure 3.

<sup>(</sup>concept life cycle model, European Operational Concept Validation Methodology, E-OCVM)

centre

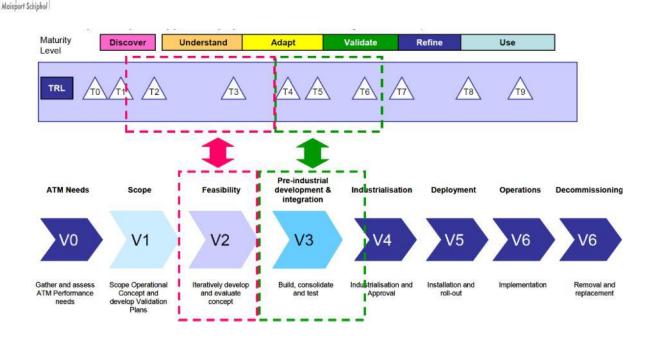

Figure 3: Principal relationship between the NASA TRLs and the E-OCVM CLM phases (source: Eurocontrol, 2018)

### 2.2 Management of the research agenda

The initial version of the research agenda was released in 2006, when KDC was established as a foundation. Since then the KDC research agenda is maintained by means of annual updates (or in some cases two releases per year).

The KDC programme is a multi-annual programme, managed on an annual budget basis. Priorities are set by the KDC-Board on the basis of proposals made by the MT-KDC, and in consultation with the Dept. of Infrastructure and Water Management. These priorities indicate the sequence of execution for the studies. The sequence depends on a number of factors. One aspect is the time to mature the assignment, i.e. the time lapse between the initial description of the development subject, and the approved assignment for the call for proposals. Depending on the subject and the parties involved this process may take several months. Underlying this process ofcourse are the main driving factors in the priority setting: the urgency of the stated problem and/or the assumed benefit of the development in the short term.

Characteristics of KDC studies are:

- The assignment must have a direct relationship with the development of the Mainport Schiphol.
- Multiple stakeholders share the requirement(s).
- Collaboration between different (knowledge/expertise) parties is needed to achieve a good/applicable solution (multidisciplinary solutions).
- The KDC studies focusses on the development of so-called "building blocks1" that can be developed in a period of one to two years.

For each subject, a short description is given as well as the expected results and involved parties.

1 In this document a "building block" is defined as an air traffic management solution that consists of a combination of changes in the area of systems, procedures, and training.

### 2.3 Strategic Objectives

The multi-annual research agenda addresses five development themes, each for which strategic objectives have been defined. The five development areas are:

- 1. Safe Airspace and Airport Navigation
- 2. Environmental Sustainability
- 3. Airline & Airport Operational Efficiency
- 4. Capacity Management
- 5. Airspace Redesign & Innovation

In the following chapters each development area addresses its strategic objective for the 2021 - 2025 timeframe.

### 2.3.1 Safe Airspace and Airport Navigation

Within the theme of safety, not much research has been conducted in the context of KDC in recent years. The cause is partly due to the fact that the ISMS was set up in the period 2017 - 2018, with its own research budget and activities. In addition, NLR has a substantial research budget for safety-related research that is supports technological innovation themes (such as drones, autonomous flight / unmanned aviation).

However, safety-related research is of strategic importance for the development future ATM concept as well. The focus in the KDC is on the development of new applications that do not necessarily result from operational incidents (as in the case of ISMS) or the advent of new technology. The transition to trajectory based operations, or plan-based ATM, and the implementation of data link changes the role of the human in the ATM system and offers new possibilities to develop security-enhancing applications. This includes increasing the integrity of communication and conformance monitoring applications.

The KDC objective for the development of Safe Airspace and Airport Navigation in the 2021 - 2025 timeframe is:

Support safety validation aspects of the future ATM concept and develop safety enhancing building blocks.

### 2.3.2 Environmental Sustainability

The development of innovative solutions to limit noise annoyance<sup>2</sup> and to reduce emissions are important for the future of Schiphol. For the period up to 2030, solutions in this area are expected based on three technological developments:

a) The increased use of the navigation capabilities of modern aircraft

b) Developing advanced planning systems and including environmental aspects in planning and flight execution

c) Chain optimization (improved collaboration between stakeholders) and early influencing of traffic

These developments are intended to ensure that traffic is handled as much as possible from environmentally-preferred runways and that, as much as possible, noise-optimized routes and profiles are flown.

<sup>&</sup>lt;sup>2</sup> Note: The overall programme to reduce noise annoyance is published on <u>minderhinderschiphol.nl</u> (in Dutch).

The KDC objective for the development of Environmental Sustainability in the 2021 – 2025 timeframe is:

Support the development of building blocks that generate environmental benefits on the basis of advances in aircraft capabilities, technology and collaboration between stakeholders.

### 2.3.3 Airline & Airport Operational Efficiency

It is important for Schiphol's hub function that a high degree of reliability of the transfer process can be guaranteed under all circumstances. This requires that the airport's capacity is made insensitive to weather conditions as much as possible. In addition, it is important that capacity-**limiting weather conditions can be "forecasted" as reliably and as early as** possible as well.

It can be expected that as Schiphol airport operates close to the limits of its, that the hub function will become more sensitive to disruptions. For the hub function it is important that the "connected flights" can be "safeguarded" from delays that are the result of disruptions and non-nominal conditions. The priority sequencing concept can support the hub function, even when the airport is close being saturated (with increasing network delay as a result).

The KDC objective for the development of Airline & Airport Operational Efficiency in the 2021 – 2025 timeframe is:

Support the further increase of the operational reliability of the hub function of Schiphol airport and support the increase of the operational efficiency for the airlines.

### 2.3.4 Capacity Management

The development of capacity management involves improved insight in available capacity (given weather conditions and other variables) and tailoring demand to the capacity as closely as possible, based on common agreed performance indicators. The development of capacity management is a complex matter, as it affects all parts of the Dutch ATM system, and is strongly influenced by decisions made within the European network.

For the future of Schiphol, it is important that the capacity management functions are state-of-the-art, so that local capacity decisions can be made in appropriate planning stages as part of the European planning processes. The development of capacity management also has strong interfaces with Schiphol's environmental objectives, because it affects the predictability of traffic handling and the planned use of runways (within the agreed framework).

The KDC objective for the development of Capacity Management the 2021 – 2025 timeframe is:

Support the development of multi-stakeholder capacity management processes with the aim to support the transition to the future ATM concept and to support the hub function of Schiphol airport.

### 2.3.5 Airspace Redesign & Innovation

Airspace re-design supports multiple strategic goals, both civil and military. With regard to the civil objectives, it is not only about improving the environment, capacity and safety performance of Schiphol, but also about the development of the regional airports of

Rotterdam, Eindhoven, Maastricht, Groningen and Lelystad. The airspace re-design program not only creates a new design for the airspace, it also identifies the technological innovations needed to achieve the performance targets.

A number of the innovations identified within the airspace re-design program concern technological innovations that have been worked on for some time in the context of KDC. This creates a direct relationship between the strategic goals of the KDC (with Schiphol as focus) and the airspace re-design program.

One of the key developments in the airspace re-design program is the transition to a new TMA concept, which is based on fixed approach routes with continuous descent profiles, and SIDs with continuous climb profiles. It is foreseen that the transition to the new TMA concept requires a new operational concept, and several technological innovations.

The KDC objective for the development of Airspace Redesign & Innovation the 2021 – 2025 timeframe is:

Support the development of, and the transition towards, the new TMA concept, which is based on fixed approach routes with continuous descent profiles, and SIDs with continuous climb profiles.

### 2.4 Airspace user perspective

A literature study, conducted in the analysis phase of the first version of the research agenda, revealed which of the research is relevant for each sector partner. Top priority for KLM as a hub carrier is to guarantee reliable capacity of the traffic stream in- and outbound Schiphol. Capacity and reliability of the capacity (also called "sustainability") ensure passenger connections can be realised. An important part of the research agenda is aimed at improving the sustainability whilst increasing the capacity for various meteorological conditions.

For airspace users, including KLM, in general it is important to continuously improve its efficiency. Part of the research agenda aims at efficiency improvements at Schiphol and in the Dutch FIR in strong cooperation with LVNL and RSG.

The figure below (figure 4) shows that certain runway combinations (indicated by roman numbers) deliver less hourly capacity compared to other runway combinations. Furthermore, the visibility conditions (good, marginal and poor) also have significant influence on the available capacity. Not all runway combinations are always available. Usage of less favourable runway combinations can result in reduced capacity. The KDC research aims to increase airport capacity and sustainability as indicated by the arrows in figure 4.

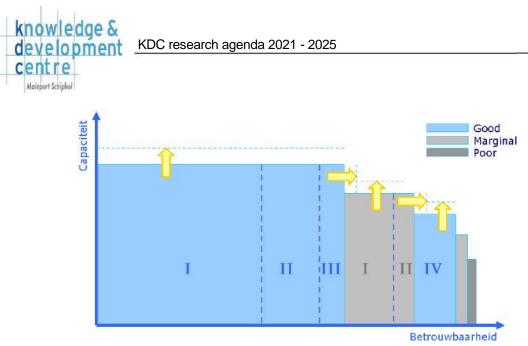

Figure 4: Sustainability (reliability of the capacity) vs. Capacity

### 3 Planned activities for 2021 and 2022

The activities which will take place in 2021/2022 are the result of the priority setting by the KDC board within the 2021 - 2025 programme. Two types of activities can be distinguished in 2021:

- a) Conceptual structuring of a new area or a new development
- This type of study is applicable to subjects (or rather development areas) that potentially include a large number of building blocks (or rather functional changes). Conceptual structuring can also be labelled as an "inventory" type of study, making an inventory of potential solutions, and classification on the basis of performance indicators.
- b) Development of a building block Studies which address a specific application or function are considered to be development of "building block development". Examples are studying the feasibility of a holding support function for ACC, or studying the benefits of ASAS Interval Management.

### 3.1 Summary of main activities

Below a summary is given of the subjects which are put forward for development in 2021/2022 on the basis of priorities that have been set by the KDC board:

A. Safe Airspace and Airport Navigation

### 1. Air-Ground datalink implementation strategy

This study will consist of a re-run of a study that was performed in 2015. In 2015 an analysis was made to investigate whether there were potential candidate datalink applications that would have a business case for implementation on AAA, prior to its decommissioning in 2022. It turned out that there were no such applications. Now, five years later, this question is still relevant, but within the context of iCAS, the AAA replacement system, and within the context of the airspace redesign. The study has been listed as a safety enhancing application, and this is a major aspect of attention in this follow-up study. It is expected that this study will see follow-up developments in the 2022 – 2025 timeframe. For more information see section 4.1.1.

B. Environmental sustainability

### 2. Future runway use (continued)

It is foreseen that the study conducted in 2020 will have a sequel in 2021/2022. The study in 2020 was a first iteration in a design process, seeking to optimize environmental benefits of the 3D separated route concept that is part of the airspace redesign programme's "voorkeursalternatief". It is expected that further iterations will be required in 2021/2022 in the optimization process of the "voorkeursalternatief" implementation. For more information see section 4.2.1.

#### 3. CCO High altitude SIDs (continued)

The study performed in 2020 looked into the various options of continuous climb optimization on the basis of a generic model without taking turns into account. Continuous climb profiles are part of the airspace redesign "voorkeursalternatief". It is expected that further optimizations, looking into specific SID designs will be required in the 2021/2022 timeframe. For more information see section 4.2.4.

#### 4. Traffic segregation concepts

Segregating traffic into performance classes is a way to optimize the performance of the ATM system. For instance, segregation of traffic on the basis of aircraft performance (climb-rate, speed) creates more uniformity of aircraft behaviour on arrival and departure routes, which is good for capacity. However, segregation of traffic can also add to traffic complexity, which is a clear negative for capacity. The KDC study foreseen in 2020 is a first inventory of solutions with an operational assessment of feasibility. It is expected that this study will see follow-up developments in the 2022 – 2025 timeframe. For more information see section 4.2.3.

#### 5. Steep approach runway 22

The study "Steep approach runway 22" looks into noise annoyance reduction possibilities by means of steeper glideslope angle application for approaches into runway 22. The study both looks into small increases in glideslope angle (which could be flown by the majority of aircraft types) and large increases in glideslope angle (which would require certification of aircraft and/or training of crew). For more information see section 4.2.6.

#### 6. Established on RNP procedures

The study "established on RNP procedures" is intended to be an application study of a practice that was implemented by NAV CANADA in 2018. It's a special type of procedure that will require approval from the Authorities, so airlines will have to qualify for the procedure if they want to use them.

The RNP-AR (approval required) arrival procedure provides a path to the ILS localizer intercept that can be flown with a high degree of navigation accuracy, but more importantly integrity. The RNP-AR arrival procedure will enable ANSPs with more flexibility to define the arrival route, in particular in case of parallel runway operations. Thus the procedure has potential in the area of noise annoyance reduction. For more information see section 4.2.5.

C. Capacity Management

#### 7. Collaborative demand-capacity balancing, AMAN – DMAN coupling

The study into AMAN – DMAN coupling is an inventory of potential solutions to take a more collaborative approach to capacity planning of Schiphol airport. The study looks in particular at the hub function of the airport, connecting inbound and outbound demand with capacity planning of both ANSP and airport.

The study builds on the functionality that is already available, and looks into more detailed capacity planning opportunities. It is expected that this study will see follow-up developments in the 2022 – 2025 timeframe. For more information see section 4.4.1.

### 8. Multi-airport concept (continued)

The development of the multi-airport concept is a capacity management topic within KDC, despite the fact that it has a strong relationship with the airspace redesign "voorkeursalternatief". The first study, which was performed in 2020, was an inventory type of study, looking into multi-airport capacity management principles both at strategic level and (pre) tactical level.

The subject is retained within the KDC programme in anticipation of further development of building blocks identified in the previous study, in collaboration with the airspace redesign programme. For more information see section 4.4.3.

#### 9. Traffic buffering concept

The traffic buffering concept is aimed at reduction of network delay, by means of buffering traffic in the airspace. Where network delay affects the flight execution before take-off, traffic buffering affects the flight execution after take-off. The study is expected to demonstrate benefits of application of the traffic buffering concept, within the capacity management framework. For more information see section 4.4.4.

#### **10. Dynamic Flow Management**

The dynamic management of traffic flows is a conceptual building block within the airspace redesign programme. The idea is to tactically or pre-tactically redirect traffic flows to management workload in sectors. The concept is also supporting the new TMA concept which consists of 3D separated arrival and departure routes. Dynamic traffic management supports load balancing of the arrival runways, a process that needs to be facilitated outside of the TMA. The study consists of a feasibility assessment with the network manager and adjacent centres. For more information see section 4.4.5.

D. Airspace Redesign & Innovation

#### 11. Transition to Trajectory Based Operations

The development of a transition plan towards Trajectory Based Operations (TBO) consists of a broad inventory of building blocks that pave the way to full implementation of TBO in the 2030 - 2035 timeframe. The study is related to the further development of iCAS functionality within the iTEC collaboration. It is expected that this study will see follow-up developments in the 2022 - 2025 timeframe. For more information see section 4.5.1.

#### 12. Transition to high capacity fixed arrival routes (continued)

The initial study into this subject resulted in a high level transition strategy. It is expected that a sequel to the initial study is needed: the development of a detailed plan for phase 1 (preparation) and phase 2 (initial deployment of high capacity fixed arrival routes) is needed. For more information see section 4.5.2.

#### 13. TMA Merging and sequencing concept

Within the KDC framework several studies have been performed to develop merging and sequencing solutions within the TMA. Both ground based and flightdeck based solutions have been developed. Taking into account the transition to time based separation (TBS) on final approach, a new concept for merging and sequencing in the TMA needs to be developed and tested. This new concept must explore both ground based and flightdeck based solutions. For more information see section 4.5.3.

### 3.2 **Priority setting**

As the KDC has a limited budget, compared to the scope and content of the programme, priorities need to be set (factors playing a role in the setting of priorities are described in section 2.2). Within the currently known subjects, in the 2021 - 2025 timeframe, a prioritisation has been made which led to a scope for 2021/2022 (as described in section 3.1). The scope for 2021/2022 has been generously set, which means that more subjects have been proposed than likely can be executed within the 2021/2022 budget.

In figure 5 a projection of the topics, described in section 3.1, is presented in the year 2021/2022. The intention of this graph is to indicate which topics are likely to be part of the first batch of topics which will be put on the market (the topics towards the left side, or beginning, of the year) and which topics are expected to be part of consecutive batches of topics to be put on the market. As stated: subjects that are projected to be put on the market later in the year could end up to be deferred to the next year, due to lack of remaining budget in the current year.

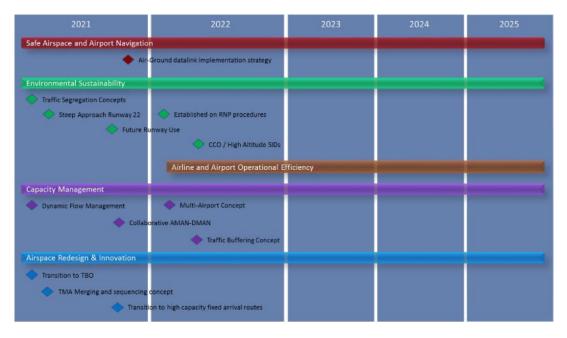

Figure 5: Overview of expected subject initiation in 2021/2022

#### Introduction:

The EUROCONTROL Link 2000+ program provides en-route Controller-Pilot Data Link Communication (CPDLC) services, which allow for the direct exchange of text-based messages between a controller and a pilot. The CPDLC messages automates routine tasks that can take up to 50% of a controller's time. In 2014, KDC completed a business case study that explored which datalink services are beneficial to the Schiphol operation below FL245, and implemented in the 2013-2016 timeframe.

Since the publication of the business case, the technology availability has changed, and the industry has advanced. According to the SESAR Concept of Operations, routine voice communications shall be replaced by 2020 for enroute traffic above FL285. As almost all traffic at Schiphol is affected by this Data Link Services Implementing Rule (DLS IR) EC29/2009, technology equipage levels are expected to be very high, if not 100%. Therefore, implementation in lower airspace is possible. The business case for implementation of the Air-Ground datalink on the current AAA system used by LVNL was negative, however in iCAS, this is expected to be different. In 2023 iCAS will be operational, opening up new possibilities for the implementation of air-ground datalink.

#### Goal / Expected benefit:

The goal of implementing air-ground datalink is to increase capacity and safety in the airspace below FL245. This is done by replacing routine RT contact (e.g. transfer of control -, weather (QNH, wind data) -, or direct-to incentives) by text-based messages. The expected benefit is a reduced ATCo workload, and increased reliability as a result of redundant communication channels.

#### Assignment:

With the (upcoming) full equipage of airline datalink technology in accordance with DLS IR, investigate which Datalink services are beneficial to the Schiphol operation below FL245. Special focus should be applied on routine messages, such as: The transfer of control at the IAF, weather information such as wind data, and direct-to incentives. An implementation strategy should be created, outlining how the technology will be implemented into iCAS, and at what moment in time.

#### Short term objective:

An implementation strategy that outlines the transition from RT communication to (partially) sending commands over the air-ground datalink in the lower airspace.

#### Midterm/Long term objective:

Operational trial which demonstrates the technical feasibility of routine instructions via datalink instead of voice communications.

Involved parties: KLM, RSG, LVNL, Dept. of I&W, KNMI

Introduction:									

With increasing traffic demand, and increasing concerns about environmental impact the aviation sector has to develop a concept which is future prove, meeting existing and new stakeholder requirements. The main requirements can be categorized as follows:

- Stable and predictable airport operations in order to optimally use airport infrastructure and resources (RSG)
- Minimal airport delays and punctuality of the operation (no-connection rate as low as possible (airlines)
- Stable airport operations by predictable traffic flows (LVNL).
- Respected environmental regulations: handling traffic on the preferred runways and limited fourth runway movements (environment and surrounding communities).
- Operating the airport in an environmentally sustainable manner (governmental bodies).

#### Goal / Expected benefit:

To develop a concept for future runway use which ensures stable airport operations within the boundaries of the environmental regulations and enables the hub-function of Schiphol.

Assignment:

- Develop a concept for future runway use which ensures stable airport operations within the boundaries of the environmental regulations and enables the hub-function of Schiphol. In collaboration with airport and airline representatives and TWR/APP ATCo' s
- Evaluate the alternative concepts on the basis of the above mentioned KPIs

#### Short term objective (first year):

Support near term policy development and decision making.

#### Midterm/Long term objective:

Modernize the runway use concept to meet future safety, environmental and capacity objectives.

Involved parties: KLM, RSG, LVNL

Outbound traffic segregation is the concept of segregating traffic on the basis of aircraft noise, aircraft performance or runway load balancing. In case of noise segregation, the noisy or heavy aircraft can be assigned to the noise preferred runway, whereas the less noise producing aircraft are assigned to the secondary runway. A similar strategy can be applied for segregation on the basis of aircraft performance, which can optimize runway throughput through optimal traffic mix sequences. A third option is traffic segregation based on runway load balancing. As there is almost never a perfect 50/50 division between east/west departing traffic, currently departure capacity is lost due to the coupling between runway and destination. If e.g. eastbound departures could also depart from the western departure runway in a start peak, the traffic load of the primary and secondary runway can be spread more equally increasing departure capacity.

However, there are many limitations, especially with regards to maintaining capacity, that need to be explored and addressed. One of the prerequisites is that the noise preferred departure runway during a start peak has active SIDs to all TMA sectors, where currently there is an east/west split active when operating two departure runways. This is known as a dual SID concept, in this concept outbound traffic can be fed to one sector from two different runways.

This study comprises of a feasibility study to the traffic segregation concept for Schiphol airport

Goal / Expected benefit:

Study the feasibility of the traffic segregation concept for Schiphol airport.

#### Assignment:

Develop a concept of outbound traffic segregation on the basis of noise load distribution and/or performance. After the concept development, assess whether or not the principal is operationally feasible, and what measures (tools, practices, etc.) are needed for traffic segregation to be implemented.

Short term objective: Produce a feasibility study

*Midterm/Long term objective:* Improve the spreading of aircraft noise over the noise preferred runways by means of traffic segregation.

Involved parties: KLM, RSG, LVNL, Dept. of I&W

### 4.2.4 CCO High altitude SIDs (continued)

KDC PoC	Evert Westerveld			1'		1'	
Financial Partner	DGLM						

#### Introduction:

The PCP and PBN Regulation require to implement RNAV routes in the Schiphol TMA with defined lateral navigation standards. SIDs at EHAM are already designed to RNAV1 standards. The goal is to design routes with a minimum 6% fixed climb profile for all aircraft types. The SIDs will be vertically and horizontally constrained with PBN design criteria, separated from all other routes. This 3D separation of inbound and outbound routes is expected to de-complex the TMA operations, and to deliver the maximum benefits in terms of safety, capacity and environmental sustainability.

It is foreseen that departure routes will be optimized above an altitude of typically 6000 ft. The connection to this upper layer in the TMA must be made by means of optimized continuous climb profiles.

#### Goal / Expected benefit:

Optimization of departure routes in the Schiphol TMA, based on continuous climb departures, making use of the advantages of precision navigation and increased trajectory uniformity. The goal is to support design options for the TMA with increased performance with respect to environmental sustainability and capacity.

#### Assignment:

Develop departure route design options for the top four preferential runway combinations at EHAM considering the following aspects:

- 1. RNP1 navigation performance
- 2. Increased climb profile uniformity:
  - a. Climb profiles that at least 95% of the aircraft can fly
  - b. Climb speed restrictions (if required)
- 3. Traffic bundling: Extended centre-line climb options (varying from 3000 ft 6000 ft)

The route design options need to be assessed in terms of capacity, track-miles and noise effects (indicative).

#### Short term objective:

Feasibility of the concept as a major building block in airspace restructuring for the 2023+ deployment timeframe.

#### Midterm/Long term objective:

A safe and environmental sustainable TMA route structure that takes advantage of new technologies, providing high capacity to the airspace users.

#### Involved parties: KLM, RSG, LVNL, Min. I&M

### 4.3 Airline and Airport Operational Efficiency

4.3.1 Inbound priority sequencing									
Ref. Ext. Programme	-	TRL	3						
Customer	KDC Board	Lifecycle phase	Feasibility assessment						
KDC Board Approval	3-12-2019	Performance Targets	S	Ec	Es	Env			
KDC PoC	Evert Westerveld		-	1'	1'	-			
Financial Partner	DGLM								
Goal / Expected benefit									

Expected benefits are in the area of efficiency.

Introduction:

Traffic flows inbound Schiphol are currently planned on a first-come-first-serve basis. Traffic is planned in such way to optimize runway capacity. No airline priorities are taken into account. 80% of the passengers onboard KLM aircraft are transfer passengers. Realizing passenger connections is therefore very important for KLM. Inbound KLM traffic has different values based on passenger flows and individual value of passengers.

In the future ATM system, inbound traffic flows will be handled based on the value of individual flights (ref. AAA replacement business case). The Arrival Management function will take airline priorities into account and traffic flows will be built upon these priorities. This process is dynamic, priorisation of individual flights shall be possible from preflight to the latest moment LVNL can accommodate prioritization. Priorisation of traffic flows inbound Schiphol shall be done as early as possible, the planning based on this priorisation shall be maintained in the NL-FIR.

#### Assignment:

Define, develop and test an experimental arrival management function which takes airline priorities into account. The study shall be done sequentially in the following defined steps:

- Case study to identify the possibilities & benefits when LVNL prioritizes KLM flights based on airline priorities. In this initial step the studies performed in 2004/2005 (Inbound Priority Sequencing) should be taken into account as background material.
- 2. Identify which value information is needed to support the planning process based on airline priorities.
- 3. Define a concept of operations to handle KLM traffic based on airline priorities.
- 4. Small scale trial to test concept with KLM flights
- 5. Full scale trial to handle traffic based on KLM priorities
- 6. Define a plan including concept to enable trading of priorities between airlines.

For step 1 to 5 it is assumed that priorisation between inbound flights can only be done intra-airline.

#### Short term objective (first year):

Steps 1, 2 and 3 are expected in the short term objective.

*Midterm objective (two – three years):* Steps 4 is expected in the midterm objective.

Long term objective (> three years): Steps 5 and 6 are expected in the long term objective.

Involved parties: KLM, LVNL, TU-Delft

Financial Partner	DGLM								

Flight & Flow Information for a Collaborative Environment (FF-ICE) is a real time data exchange system in which actual airspace and aircraft parameters are shared to support ATM operations. It is an ICAO proposal that should replace the current ICAO flight plan standard. FF-ICE is a 4D trajectory planning tool that can increase flight planning reliability and 4D optimization. FF-ICE also opens up possibilities to plan trajectories through restricted areas that are available at the planned crossing moment. This reduces the amount of fuel that needs to be reserved for the detour, thereby decreasing emissions. Lastly, FF-ICE is a far more collaborative format that makes it easier for the ATM community to exchange information. All parties involved in the ATM process will have a great level of awareness to where an aircraft is at what point in time. (ICAO.int, 2011)

#### Goal / Expected benefit:

FF-ICE is expected to enable shorter and safer route planning, and an increased data exchange between ATM partners. As a result, FF-ICE has many expected benefits. First off all, flight plan reliability will be increased by reducing the time difference between the flight plan and the actual flight time. Furthermore, it is expected to reduce on board fuel reserves, which reduces emissions. Lastly, it is expected that the planned arrival time of aircraft at the FIR boundary is more reliable.

#### Assignment:

Construct an implementation strategy, detailing what measures need to be taken to implement FF-ICE in the Dutch FIR.

#### Short term objective:

An implementation strategy for the ATM actors in the Dutch FIR.

#### Midterm/Long term objective:

Dynamic 4D flight planning; enabling shorter and safer routings, reduction of emissions, and increased punctuality with respect to the flight plan.

#### Involved parties: KLM, RSG, LVNL, Dept. of I&W

KDC Board Approval		Performance Targets	S	Ec	Es	Env			
KDC PoC			$\checkmark$	$\checkmark$	-	$\checkmark$			
Financial Partner	DGLM								

#### Introduction:

In 2008 a KDC study has been performed to research increasing capacity during marginal and low visibility conditions. The study requires a follow-up based on the current situation, to see if potential solutions can be identified in increasing capacity during these conditions. Given the time elapsed since 2008, new technologies have become available, new systems have been implemented, and new developments have taken place. These developments warrant a new look into opportunities to increase capacity under low visibility conditions.

Goal / Expected benefit: Increase the resilience of the Schiphol operation by increasing capacity during marginal/low visibility conditions. As a side-benefit this also allows for an increased use of preferential runways when two landing/departure runways are in use.

Assignment: This project aims at updating the status of the solutions in the report based on the current situation, complemented by possible new procedures or concepts to increase capacity during LVP. As example, the following topics can be researched

- Decreasing ILS sensitive area
- Increased visual guidance during low visibility conditions
- Ground-Based Augmentation System (GBAS) for Cat. II and Cat. III operations
- Using full landing capacity during 2 + 1 runway use during BZO category C.
- Shape of ILS sensitive area
- Introduction of ILS in combination with Super Wide Aperture Antenna
- Taxi behaviour and use of runway 27

The scope of research is increasing capacity during low visibility conditions (from marginal up to BZO category D).

Short term objective: Highlight potential solutions which can increase capacity during marginal and low visibility conditions without compromising safety.

Midterm/Long term objective: Implement these solutions in order to increase resilience of Schiphol operation.

Involved parties: KLM, RSG, LVNL, Min. IenW

#### Introduction:

Schiphol airport, with its five main runways, has traditionally been an airport where arrival and departure capacity could be planned relatively independently from each other. The connection between arrival and departure capacity was dictated by the 2+1 runway use concept, but there was only limited interference between arrival and departure capacity: except for the runway use limitations, there was not much effect of the one on the other.

In the 2015 – 2019 period Schiphol started to approach it's capacity limits, not only in terms of volume but also in terms of hourly capacity. As arrival and departure peaks increasingly overlapped, hourly rates in excess of 110 movements per hour were seen, and workload started to become an issue for Schiphol Ground and Schiphol approach. The 2015 – 2019 saw an increase in tactical regulations on inbound traffic in order to manage arrival traffic bunches and related workload. This development in turn put strain on the airport's turn around process as delayed arrivals led to delayed departures of connecting flights. This cascade of delays due to overlap of peaks has a self enforcing effect on this same phenomenon: it adds to the further overlap of peaks.

The negative spiral of peak-overlap and delays, which started to show when Schiphol was operating close to its capacity, needs to be addressed by means of a more collaborative approach to demand-capacity balancing, supported by a more integrated picture of arrival and departure capacity and demand. The airport, the hub carrier, the ANSP, and the network manager should all work towards the same goal: airspace and airport capacity is planned in an integrated manner which support the hub-function: the managed connection of flights.

#### Goal / Expected benefit:

Reduction of delay, increased predictability, increased connectivity, improved airport utilisation, environmental regulation compliance

Assignment:

Describe the future collaborative arrival – departure capacity planning process, involving the airport, the hub carrier, the ANSP, and the network manager.

Short term objective: Development of a masterplan for Schiphol airport capacity management.

#### Midterm/Long term objective:

Fully collaborative capacity planning and management.

Schiphol as well as regional airports grow. Traffic streams from different airports use the same airspace. Therefore it is needed that, parallel to a new airspace design, airports are jointly managed, to efficiently use the available airspace. This concerns strategic, pre-tactical as well as tactical planning. In the strategic domain for example, currently schedules of slot regulated airports do not take other airports' schedule into account. In the pre-tactical domain, the Schiphol D-1 planning, Schiphol sector briefings, LVNL workload model, and management of disruptions can be studied.

#### Goal / Expected benefit:

The goal of this study is to propose measures for an efficient use of airspace with multiple airports. This concerns strategic, pre-tactical as well as tactical planning measures.

Assignment:

- Research how the management of traffic flows in Dutch airspace can be improved, taking in account the location and function of Dutch airports. Options under consideration are: alignment of flight schedules, coordination of peak hours, refinement of flow measures, tactical complexity management measures.
- Develop a concept for the planning and management of traffic flows.

#### Short term objective:

Produce measures that streamline the multi airport operation with regard to the project of airspace redesign.

Midterm/Long term objective:

Involved parties: KLM, RSG, LVNL, Dept. of I&W

Customer	KDC Board	Lifecycle phase	Pre-i	Pre-industrial development & integration					
KDC Board Approval		Performance Targets	S	Ec	Es	Env			
KDC PoC			$\checkmark$	$\checkmark$	-	$\checkmark$			
Financial Partner	DGLM								

Dynamic Flow Management is a concept which was introduced as a building block in the national airspace re-design programme. The idea behind dynamic flow management is to manage workload in airspace sectors dynamically by redirecting traffic flows. The concept can be applied to a optimise a variety of performance indicators, beside workload the concept can also applied to manage delay or to redirect flows to meet environmental performance indicators.

The concept of dynamic flow management differs from the traditional network management principles which is based on setting airspace capacity limitations and restricting flows on the basis of these limitations. The traditional network management principles in a way also lead to a form of flow management, as airspace users probe alternate routes to avoid delays. Dynamic flow management is intended to avoid network delay altogether through a collaborative decision making process, matching capacity and demand in a cooperative manner.

#### Goal / Expected benefit:

The operational concept of dynamic flow management gives the air traffic control organization the opportunity to dynamically optimize a wide range of performance indicators, i.e. workload, capacity, delay and environmental performance indicators.

#### Assignment:

Develop the concept of dynamic flow management in collaboration with the Network Manager, adjacent centres, and KDC partners within the framework of the future airspace concept. The concept application in the Netherlands must take into account existing capacity management developments, and define a path forward to full application. Expected results:

- Description of the concept
- Initial assessment of feasibility
- Identification of performance potential (in particular reduction of network delay and improvement of environmental performance).

#### Short term objective:

Identification of initial implementation steps within the current concept with the aim to reduce delay.

#### Midterm/Long term objective:

Full application of the concept in support of the future TMA concept with fixed arrival routes.

#### Involved parties:

KLM, RSG, LVNL, MUAC, NATS, EUROCONTROL, Dept of I&W

Report "Voorkeursalternatief 2020-2035", Version 0.9, Programma Luchtruimherziening

4.4.6 Schiphol Target Time of Arrival (TTA) Concept (continued)									
Ref. Ext. Programme	-	TRL	3						
Customer	KDC Board	Lifecycle phase	Feasibility assessment			ent			
KDC Board Approval	7-12-2018	Performance Targets	S	Ec	Es	Env			
KDC PoC	Evert Westerveld & Coen Vlasblom		-	$\checkmark$	$\checkmark$	-			
Financial Partner	DGLM								

In 2017 traffic numbers for LVNL peaked at their highest on record. More than 600,000 flights were handled by Amsterdam ACC and almost 500,000 commercial flights (without general aviation) arrived and departed at Schiphol Airport. These record traffic numbers resulted in a significant increase in delay as well. To counter these delays and looking to improve its performance.

In current operations LVNL is facing traffic demand well above the declared capacity on daily basis. Regulations are put into place to counter these Schiphol inbound traffic peaks. As such safety and orderly handling of traffic are ensured. With the increase in traffic, the delay caused by these regulations has increased as well. In 2017 Amsterdam Airport generated 13.8% of all European airport arrival ATFM delay (ATFM stands for Air Traffic Flow Management). According to the Network Manager, Schiphol Airport is one of the most congested airports in Europe and its generated delay has the largest impact on the network.1 ATFM delays are a problem for the aviation business mainly for the airline operators. Delays increase airline operating costs (cost of ATFM delay is around €80-€100 per minute) and it disrupts airline operations (including reactionary delay). Furthermore delays can disrupt airport operations (need for use of less environmentally preferable runways, gate planning, planning of ground handling, etc.). Finally the use of ATFCM-measures (regulations) decreases the planning flexibility of the European Network (due to the increased issuing of CTOT's).

To counter these delays, LVNL is seeking to increase capacity and to balance capacity & traffic demand in more efficient ways. One of the potential improvements is the use of "less stringent" regulations (potentially using higher rates and/or smaller regulation periods) by increasing the effectiveness of these regulations. In current operations, LVNLs experience is that regulations, used to reduce traffic peaks / bunches, do not always results in a sufficient safeguard for traffic overloads Often traffic peaks reoccurs before or after the planned peak moments. Different root cause generate the deviations, for example deviations in flight plan filed versus actual flown, different offset in the regulation model developed and in use by the Network Manager. Furthermore ATC in en-route sectors can issue directs to aircraft, resulting in further deviations. In addition airlines sometimes try to recover endured delays by flying more efficient (routes, heights and speeds). All mentioned root causes result in regulations (and capacity) that are managed with some conservatism to overcome these effects.

KDCs is interested in the concept of improving the regulation concept and target times solutions (TTO/TTA) as measures to increase effectiveness of regulations by preventions of bunching. TTO stands for Target Time Over (TTA Target Time Arrival) and represents the target time for a flight to enter an (regulated) airspace according to the flight profiling done by Network Manager. When pilots are able to operate more according to these times, risk of traffic bunches occurring may decrease.

In Europe some ANSP's have conducted trials for TTO/TTA (Target Time Arrival). TTO/TTA is incorporated in SESAR as one of the future operational concepts. Therefore it is expected that understanding of this concept can be acquired by a short study of already available information and trial experiences.

Goal / Expected benefit: More effective EHFIRAM regulations, less Airport ATFM delay and (in longer term) increased capacity

Assignment:

KDC requires a sort study addressing the following topics: What is the TTO/TTA concept, how does it work?

- SESAR Network Manager regulation concept
- Trials at ANSP's
- Collaboration between Network Manager, ANSP's and Airlines

#### Which performance benefits can TTO/TTA deliver

- Effectiveness of ATFCM measures (regulations)
- Improvement of the regulation model (decreasing offset/ flight plan deviations)
- Performance effects on capacity and ATFM-delay

#### Feasibility of TTO/TTA use at Amsterdam Airport Schiphol / Amsterdam ACC

- Improvement of the regulation model (decreasing offset/flight plan deviations)
- Incorporation of TTO/TTA in current and/or future operations
- Possibilities to conduct trials in current operations
- Effectiveness for non-regulated flights (e.g. intercontinental traffic)
- Relations with current and future developments (like AMAN 2.0 and XMAN-trials)

#### Short term objective:

Delivery of a report addressing the benefits and feasibility of the regulation model and TTO/TTA concepts at Amsterdam Airport Schiphol and Amsterdam ACC

#### *Midterm/Long term objective:*

Depending on the feasibility study:

Midterm objective is the conducting of one or multiple trials at Amsterdam Airport Schiphol and Amsterdam ACC

Depending on trial results: Long term objective is to introduce TTO/TTA at Amsterdam Airport Schiphol and Amsterdam ACC

Involved parties: KLM, RSG, LVNL, Dept. of I&W

#### Introduction:

LVNL has decided to join the iTEC consortium as part of its AAA replacement strategy. This approach will ensure commonality and interoperability of the LVNL (technical) ATM system (iCAS) in the future and will ensure access to innovative system components developed by the SESAR programme.

The replacement of AAA with iCAS will enable LVNL to migrate overtime towards TBO, trajectory based operations. TBO is a new operational concept which is founded on system interoperability, air-ground integration and collaborative decision making processes. The end-stage TBO concept is currently not very well defined, and subsequently the implementation date of a fully developed TBO is not yet known. The road towards the end-concept is not very clear either: there are many building blocks that fit the description as a step towards TBO, but choices about the usefulness of some of these building blocks are still to be made. One aspect that complicates matters is the perceived conceptual overlap between building blocks, this is especially true for arrival management related solutions.

#### Goal / Expected Benefit:

A structured and clear path towards trajectory based operations with respect to arrival management related building blocks.

#### Assignment:

Make an inventory of all conceptual building blocks that are related to arrival management process, describe the essential functions of these building blocks, and structure these building blocks in a roadmap towards TBO. Conceptual overlap must be identified and recommendations to reconcile these overlaps must be made. The following conceptual building blocks must be taken into account as a minimum: AMAN, XMAN, Long-range XMAN (LHR concept), Traffic buffering concept, TTO/TTA concept, RTA, CTA, COP-sequencing, Traffic debunching, Priority Sequencing, Dynamic Flow Management

#### Short term objective:

An agreed path towards TBO with beneficial near term implementation steps that are part of the end-stage TBO concept.

*Mid term / Long term objective:* Full scale deployment of TBO.

4.5.2 Transition to high capacity fixed arrival routes (continued)						
Ref. Ext. Programme	-	TRL			3

KDC Board Approval	3-12-2019	Performance Targets	S	Ec	Es	Env
KDC PoC			$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$
Financial Partner	DGLM					

#### Introduction:

In the national ATM strategy it is outlined that in 2024 traffic in the TMA is guided over fixed arrival routes with low altitude CDA's. This measure is meant to reduce noise annoyance and gaseous emissions, as the fixed arrival routes will be optimized to avoid overflying of habited areas.

Currently LVNL has published one fixed arrival route for daytime use in the Schiphol TMA: the ARTIP1X approach from ARTIP to runway 36R. In practise this fixed arrival route is not used because runway 36R is a secondary runway and can only be used during inbound peak periods: The demand during these periods is too high relative to the capacity of the ARTIP1X arrival route.

The capacity of ARTIP1X is estimated to be about 30 movements per hour. This figure however has not been validated and may also be lower. In order to be able to use fixed arrival routes in the daily operation, the capacity of fixed arrival routes needs to be increased. There are several measures to increase capacity of fixed arrival routes, for example:

- 1) Improved delivery accuracy at the IAF
- 2) Allowance of flexibility (e.g. tromboning)

For fixed arrival routes to the primary runways, merging support for approach will be required, as these routes merge traffic from two IAFs.

#### Goal / Expected benefit:

Calculate and validate the capacity of fixed arrival routes for Amsterdam airport and the benefit to capacity of the aforementioned optimizations.

#### Assignment:

- Design a rough concept of fixed arrival routes for EHAM that resemble 2024 implementation.
- Perform a real time simulation to validate the capacity of ARTIP1X and the proposed arrival routes.
- Optimize the capacity of the fixed arrival routes before Interval Management implementation, and validate the capacity benefit of the optimizations.

Short term objective: Defining the expected capacity for fixed arrival routes at Amsterdam airport.

*Midterm/Long term objective:* Capacity increase for fixed arrival routes.

Involved parties: KLM, RSG, LVNL, Dept. of I&W

4.5.3 TMA Merging and sequencing concept

The airspace redesign programme has adopted a concept for the Schiphol TMA, the area around Schiphol with a 50 km radius, which is based on fixed arrival routes and low altitude continuous descent approaches. It is foreseen that the new Schiphol TMA design will have four initial approach fixes (IAFs), entry points from where aircraft will follow the fixed arrival routes. From these four IAFs two landing runways will be fed, which means that for each runway a merging point will be part of the fixed arrival route design.

The merging of traffic is an important aspect of the fixed arrival route concept. For the approach controller, who is responsible for the safe handling of traffic in the TMA, information must be provided that separation minima are respected through-out the merging process. This information must be provided some time prior to the actual merge of aircraft pairs converging on the merge point, in order for the controller to take timely action to prevent loss of separation.

There are two main system/concept options available to support the controller with his/her merging task:

- Flightdeck Interval Management (FIM). F-IM requires aircraft equipage which supports the time/distance keeping functions between aircraft pairs. This technology has been developed but airline equipage levels are currently zero. However, American Airlines decided in 2018 to equip some 200 A321 aircraft with ADSB-IN technology in order to fly IM procedures into Phoenix, Arizona, becoming the first early adopter of the IM concept
- 2. Ground Based Interval Management. GB-IM is a comparable concept as F-IM, but guidance information (i.e. radar target or ghost indicator) is given to the controller (not to the aircraft's avionics), and the concept lacks automation. Similar to F-IM sequencing support and merging support can be provided through GB-IM.

#### Goal / Expected benefit:

Stable, safe and environmental friendly TMA operations with high capacity.

#### Assignment:

Define a preferred path forward, conceptually, for merging and sequencing process that supports the future TMA concept. Information from previous KDC studies must be taken into account. Furthermore, the current RECAT-TBS development must be taken into account. Implementation risks and workload/capacity aspects must be taken into consideration as well.

#### Short term objective:

Establishing an agreed development and implementation strategy for merging and sequencing in the Schiphol TMA.

Midterm/Long term objective:

Involved parties: KLM, LVNL, RSG, Dept. of I&W

4.5.4 Holding support for area control						
Ref. Ext. Programme	-	TRL			3	
Customer	KDC Board	Lifecycle phase	Pre-industrial development & integration			
KDC Board Approval		Performance Targets	S	Ec	Es	Env
KDC PoC	Evert Westerveld		$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$

#### Goal / Expected benefit

Holding patterns are mainly flown in non-nominal situations in order to deal with adverse weather, wind, emergencies or delays. Flying holding patterns have significant environmental, cost impact and plan stability. Optimizing the holding operation could lead to a better flow of traffic, less fuel use and improves accurate delivery for approach Schiphol.

#### Introduction:

Holding procedures keep aircrafts within a specified airspace by proscribing speed, hold entry procedures, timing and <u>rate of turn</u>. AMAN tools for area control do not offer any decision support for flying a holding pattern. Area controllers use only their expertise for an efficient holding. Awaiting further clearance from ATC, aircrafts can safely and orderly be sequenced to the runway.

#### Assignment:

- Research possibilities to provide area controllers decision support while holding (speed, timing and rate of turn while holding, taking in account separation minima). Also, take in account the available vertical view tool.

- Assess the performance of relevant options.

#### Short term objective:

Creating an overview of the available options to provide ATCOs with decision support during holdings.

#### *Midterm/Long term objective:*

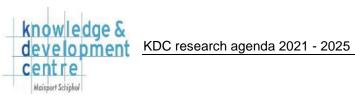

Provide ATCOs with more convenient procedures or decision support tooling in flying holding patterns

Involved parties: KLM, AAS, LVNL, Dept. of I&W, KNMI

### **Appendix A: Project Template**

Template for describing research subjects within KDC. This template differs over the years, as the format is optimized.

Ref. Ext. Programme				ss Level		
Customer	Entity which accepts and uses the result Lifecycle phase Phase in the E-OCVM meth		ethodolog			
KDC Board Approval	Date	Performance Targets	S	Ec		Env
KDC PoC	Name		1	1	1	1
Provider/Stakeholder which financially supports the project						
Introduction: Short description in common language of the research subject.						
Assignment: Short description of as which date.	signment made by the cus	tomer. What does the cu	stomer ex	cpect to	be achi	eved by
Short Term Goal (0 - 3 years): Breakdown of goals in short term, midterm and long term. The short term goal must be achieved within 0 - 3 years.						
<i>Midterm Goal (3 – 5 years):</i> This goal must be achieved within 3- 5 years.						
<i>Long term Goal:</i> This goal must be achieved within 5 – 10 years.						
Relationship with other projects/research: When considered essential to understanding the place of this research subject in relation to other developments, this paragraph can be added to the description.						
<i>Involved Parties:</i> A list of parties which actively participate in the research.						
Background information: Any other relevant information which helps understanding the relevance of the research subject.						
<i>Source:</i> The source of the research.						
Result report: Reference to the outcome of the project.						

#### Technology Readiness Levels (TRL):

TRLs are a systematic metric/measurement system that supports assessment of the maturity of a particular technology and the consistent comparison of maturity between different types of concept. The definitions of the different TRL levels are given in the table below.

1. Basic principles observed and reported	Lowest level of technology readiness. Scientific research begins to be translated into applied research and development. Example might include paper studies of a technology's basic properties.
2. Technology concept and/or application formulated	Invention begins. Once basic principles are observed, practical applications can be invented. The application is speculative and there is no proof or detailed analysis to support the assumption. Examples are still limited to paper studies.
3. Analytical and experimental critical function and/or characteristic proof of concept	Active research and development is initiated. This includes analytical studies and laboratory studies to physically validate analytical predictions of separate elements of the technology. Examples include components that are not yet integrated or representative.
4. Component and/or breadboard validation in laboratory environment	Basic technological components are integrated to establish that the pieces will work together. This is relatively "low fidelity" compared to the eventual system. Examples include integration of 'ad hoc' hardware in a laboratory.
5. Component and/or breadboard validation in relevant environment	Fidelity of breadboard technology increases significantly. The basic technological components are integrated with reasonably realistic supporting elements so that the technology can be tested in a simulated environment. Examples include 'high fidelity' laboratory integration of components.
6. System/subsystem model or prototype demonstration in a relevant environment	Representative model or prototype system, which is well beyond the breadboard tested for TRL 5, is tested in a relevant environment. Represents a major step up in a technology's demonstrated readiness. Examples include testing a prototype in a high fidelity laboratory environment or in simulated operational environment.
7. System prototype demonstration in an operational environment	Prototype near or at planned operational system. Represents a major step up from TRL 6, requiring the demonstration of an actual system prototype in an operational environment, such as in an aircraft, vehicle or space. Examples include testing the prototype in a test bed aircraft.
8. Actual system completed and 'flight qualified' through test and demonstration	Technology has been proven to work in its final form and under expected conditions. In almost all cases, this TRL represents the end of true system development. Examples include developmental test and evaluation of the system in its intended weapon system to determine if it meets design specifications.
9. Actual system 'flight proven' through successful mission operations	Actual application of the technology in its final form and under mission conditions, such as those encountered in operational test and evaluation. In almost all cases, this is the end of the last "bug fixing" aspects of true system development. Examples include using the system under operational mission conditions.

### Appendix B: Relationship between TRL levels and the ATM System Development Phases
